

# TPS23755 IEEE 802.3at PoE PD with No-Opto Flyback DC-DC Controller

## 1 Features

- Complete IEEE 802.3at PD Solution for Type 1 PoE
  - Ethernet Alliance (EA) Logo Certified Designs Available
  - Robust 100-V, 0.36-Ω (typ) Hotswap MOSFET
  - Programmable Classification Level
- Integrated PWM Controller with 0.77-Ω (typ) 150-V Power MOSFET
  - Flyback Controller with PSR
    - Supports CCM Operation with Secondary Side Diode Rectifier
    - ±3% (typ, 12-V Output) Load Regulation (5%-100% range)
  - Supports Low-side Switch Buck Topology
  - Adjustable Switching Frequency with Synchronization
  - Advanced Startup
  - Programmable Slew Rate and Frequency Dithering for Enhanced EMI Reduction
- Secondary Side Adapter Priority Control with Smooth Transition
- -40°C to 125°C Junction Temperature Range
- Small 6-mm x 4-mm VSON Package

## 2 Applications

- IEEE 802.3at Compliant Powered Devices
- Security Cameras
- IP Phones
- Access Points

## 3 Description

The TPS23755 device combines a Power over Ethernet (PoE) powered device (PD) interface, a 150-V switching power FET, and a current-mode DC-DC controller optimized for flyback topology. The high level of integration along with primary side regulation (PSR), spread spectrum frequency dithering (SSFD), and advanced startup makes the TPS23755 an ideal solution for size-constrained applications. The PoE implementation supports the IEEE 802.3at standard as a 13-W, Type 1 PD.

The PSR feature of the DC-DC controller uses feedback from an auxiliary winding for control of the output voltage, eliminating the need for external shunt regulator and optocoupler. It is optimized for operation with secondary side diode rectifier (typically 12-V output or higher). Typically, the converter operates in continuous conduction mode (CCM) at a switching frequency of 250 kHz.

SSFD and slew rate control helps to minimize the size and cost of the EMI filter. Advanced Startup allows the use of minimal bias capacitor while simplifying converter startup and hiccup design.

Secondary auxiliary power detect capability provides priority for a secondary side power adapter, while ensuring smooth transition to and from PoE input power, with no efficiency or thermal trade-off.

The DC-DC controller features internal soft-start, slope compensation, and blanking. For non-isolated applications, the buck topology is also supported by the TPS23755.

Table 1. Device Information<sup>(1)</sup>

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TPS23755	VSON (24)	6.00 mm x 4.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

## 5 Product Information

## 6 Pin Configuration and Functions

### Pin Functions

PIN		I/O	DESCRIPTION
NO.	NAME		
1	RSNS	O	Switching Power FET source connection. Connect to the external power current sense resistor.
2	CP	O	CP provides the clamp for the primary side regulation loop. Connect this pin to the lower end of the second primary side winding of the transformer.
3	GND	—	Power ground used by the flyback power FET gate driver and CP. Connect to RTN.
4	SRR	I	Switching FET Gate sinking current input, used for EMI control. Connect a resistance from SRR to GND to control the V <sub>ds</sub> rate of rise.
5	SRF	I	Switching FET Gate sourcing current input, used for EMI control. Connect a resistance from SRF to VB to control the V <sub>ds</sub> rate of fall.
6	VB	O	5-V bias rail for the switching FET gate driver circuit. For internal use only. Bypass with a 0.1- $\mu$ F ceramic capacitor to GND pin.
7	AUX_D	I	Auxiliary supply detect, internally pulled-up to approximately 5V. Pull this pin low, typically through an optocoupler from the secondary side, to step down the output voltage of the DC-DC converter when a secondary side auxiliary supply is connected.
8	CS	I	DC-DC controller current sense input. Connect directly to the external power current sense resistor.
9	DTHR	O	Used for spread spectrum frequency dithering. Connect a capacitor from DTHR to RTN and a resistor from DTHR to FRS. If dithering is not used, short DTHR to VB pin.
10	FRS	I/O	This pin controls the switching frequency of the DC-DC converter. Tie a resistor from this pin to RTN to set the frequency.
11	RTN	—	RTN is the output of the PoE hotswap and the reference ground for the DC-DC controller.
12	VSS	—	Negative power rail derived from the PoE source.
13	VDD	—	Source of DC-DC converter start-up current. Connect to VPD for most applications.
14	VPD	—	Positive input power rail for PoE interface circuit. Derived from the PoE source. Bypass with a 0.1 $\mu$ F to VSS and protect with a TVS.

**Pin Functions (continued)**

PIN		I/O	DESCRIPTION
NO.	NAME		
15	DEN	I/O	Connect a 24.9-kΩ resistor from DEN to VPD to provide the PoE detection signature. Pulling this pin to VSS during powered operation causes the internal hotswap MOSFET to turn off.
16	CLS	O	Connect a resistor from CLS to VSS to program the classification current.
17	NC	—	No connect pin. Leave open.
18	FB	I	Converter error amplifier inverting (feedback) input. It is typically driven by a voltage divider from the auxiliary winding. Also connect to the COMP compensation network.
19	COMP	O	Compensation output of the DC-DC convertor error amplifier. Connect the compensation networks from this pin to the FB pin to compensate the converter.
20	AUX_V	O	AUX_V works with AUX_D to step down the output voltage setting of the DC-DC converter when an auxiliary supply is detected. Typically connected to FB pin through a resistor which defines the new voltage setting.
21	VCC	I/O	DC/DC converter bias voltage. The internal startup current source and converter bias winding output power this pin. Connect a 1μF minimum ceramic capacitor to RTN.
23	NC	—	No connect pin. Leave open.
24	DRAIN	O	Drain connection to the internal switching power MOSFET of the DC/DC controller.
-	PAD	—	The exposed thermal pad must be connected to VSS. A large fill area is required to assist in heat dissipation.
A1-A4	ANCHORS	—	Should be soldered to PCB for mechanical performance. These pins are not connected internally.

## 7 Specifications

### 7.1 Absolute Maximum Ratings

Voltage are with respect to  $V_{VSS}$  (unless otherwise noted)<sup>(1)</sup>

		MIN	MAX	UNIT
Input voltage	VDD, VPD, DEN, GND, RTN <sup>(2)</sup>	-0.3	100	V
	VDD to RTN	-0.3	100	
	AUX_D, FB, CS, all to RTN	-0.3	6.5	
	SRF to GND	-0.3	6.5	
Voltage	CLS <sup>(3)</sup>	-0.3	6.5	V
	FRS <sup>(3)</sup> , COMP <sup>(3)</sup> , VB <sup>(3)</sup> , SRR <sup>(3)</sup> , DTHR <sup>(3)</sup> , RSNS <sup>(3)</sup> , AUX_V <sup>(3)</sup> , all to RTN	-0.3	6.5	
	VCC to RTN	-0.3	19	
	DRAIN to GND	-0.3	150	
	CP to GND	-0.3	60	
Sourcing current	VB, VCC	Internally limited		mA
	CLS	35		
	COMP	Internally limited		
Sinking current	RTN	Internally limited		mA
	DEN	1		
	AUX_V	5		
	COMP	Internally limited		
$I_{DRAIN}$	Switching DRAIN peak current limit	2		A
	Switching DRAIN peak current limit, Buck topology with 16% duty-cycle	3		
Peak sourcing current	CP	1.5		A
$T_{J(max)}$	Maximum junction temperature	Internally Limited		°C
$T_{stg}$	Storage temperature	-65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2)  $I_{RTN} = 0$  for  $V_{RTN} > 80$  V.

(3) Do not apply voltage to these pins.

### 7.2 ESD Ratings

		VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±2000
		Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±500
		IEC 61000-4-2 contact discharge <sup>(3)</sup>	±8000
		IEC 61000-4-2 air-gap discharge <sup>(3)</sup>	±15000

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

(3) ESD per EN61000-4-2, applied between RJ-45 and output ground of the TPS23755EVM-894 evaluation module. These were the test levels, not the failure threshold.

### 7.3 Recommended Operating Conditions

 Voltage with respect to  $V_{VSS}$  (unless otherwise noted)

		MIN	NOM	MAX	UNIT
Input voltage range	VDD, VPD, RTN, GND	0		57	V
	VCC to RTN	0		16	
	AUX_D to RTN	0		VB	
	CS to RTN	0		2	
	DRAIN to GND	0		125	
	CP to GND	0		45	
Sinking current	RTN			350	mA
Peak current limit	DRAIN, RSNS			1.6	A
	DRAIN, RSNS, Buck topology with 16% duty-cycle			2.5	
Peak sourcing current	CP			500	mA
Capacitance	VB <sup>(1)</sup>	0.08	0.1		μF
	VCC	0.8	1		
Resistance	CLS <sup>(1)</sup>	30			Ω
	SRF to VB			100	
	SRR to GND			15	
Synchronization pulse width input (when used)	FRS	35			ns
T <sub>J</sub>	Operating junction temperature	−40		125	°C

(1) Voltage should not be externally applied to this pin.

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		TPS23755	UNIT
		RJJ (VSON)	
		24 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	34.7	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	24.5	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	14.5	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	6.4	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	14.5	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	6.4	°C/W

 (1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).

## 7.5 Electrical Characteristics: DC-DC Controller Section

Unless otherwise noted,  $V_{VDD} = 48\text{ V}$ ;  $R_{DEN} = 24.9\text{ k}\Omega$ ;  $R_{FRS} = 60.4\text{ k}\Omega$ ; CLS, AUX\_V, RSNS and DRAIN open; CS, AUX\_D, and GND connected to RTN; SRR connected to GND; SRF, FB and DTHR connected to VB;  $C_{VB} = 0.1\text{ }\mu\text{F}$ ;  $C_{CC} = 1\text{ }\mu\text{F}$ ;  $8.5\text{ V} \leq V_{VCC} \leq 16\text{ V}$ ;  $-40^\circ\text{C} \leq T_J \leq 125^\circ\text{C}$ . Positive currents are into pins unless otherwise noted. Typical values are at  $25^\circ\text{C}$ .

$[V_{VSS} = V_{RTN}$  and  $V_{VPD} = V_{VDD}]$  or  $[V_{VSS} = V_{RTN} = V_{VPD}]$ , all voltages referred to  $V_{RTN}$  and  $V_{GND}$  unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>DC-DC SUPPLY (VCC)</b>						
$V_{CUVR}$	Undervoltage lockout	$V_{VCC}$ rising	8	8.25	8.6	V
$V_{CUVF}$		$V_{VCC}$ falling	5.85	6.1	6.25	V
$V_{CUVH}$		Hysteresis <sup>(1)</sup>	2	2.15	2.5	V
$I_{RUN}$	Operating current, converter switching	$V_{VCC} = 10\text{ V}$ , $V_{FB} = V_{RTN} = V_{RSNS}$ , DRAIN with 2-k $\Omega$ pull up to 95 V		2.0	2.35	mA
$t_{ST}$	Start-up time, $C_{CC} = 1\text{ }\mu\text{F}$	$V_{DD} = 10.2\text{ V}$ , $V_{VCC}(0) = 0\text{ V}$	0.5	1.0	2.5	ms
		$V_{DD} = 35\text{ V}$ , $V_{VCC}(0) = 0\text{ V}$	0.5	0.80	1.5	ms
$V_{VC\_ST}$	VCC startup voltage	Measure $V_{VCC}$ during startup, $I_{VCC} = 0\text{ mA}$	11	13	15.5	V
<b>DC-DC TIMING (FRS)</b>						
$f_{SW}$	Switching frequency	$V_{FB} = V_{RSNS} = V_{RTN}$ , Measure at DRAIN	223	248	273	kHz
$D_{MAX}$	Duty cycle	$V_{FB} = V_{RSNS} = V_{RTN}$ , Measure at DRAIN	75%	77.5%	80%	
$V_{SYNC}$	Synchronization	Input threshold	2	2.2	2.4	V
<b>FREQUENCY DITHERING RAMP GENERATOR (DTHR)</b>						
$I_{DTRCH}$	Charging (sourcing) current	0.5 V < $V_{DTHR} < 1.38\text{ V}$	$3 \times I_{FRS}$			$\mu\text{A}$
			47.2	49.6	52.1	$\mu\text{A}$
$I_{DTRDC}$	Discharging (sinking) current	0.6 V < $V_{DTHR} < 1.5\text{ V}$	$3 \times I_{FRS}$			$\mu\text{A}$
			47.2	49.6	52.1	$\mu\text{A}$
$V_{DTUT}$	Dithering upper threshold	$V_{DTHR}$ rising until $I_{DTHR} > 0$	1.41	1.513	1.60	V
$V_{DTLT}$	Dithering lower threshold	$V_{DTHR}$ falling until $I_{DTHR} < 0$	0.43	0.487	0.54	V
$V_{DTPP}$	Dithering pk-pk amplitude		1.005	1.026	1.046	V
<b>ERROR AMPLIFIER (FB, COMP)</b>						
$V_{REFC}$	Feedback regulation voltage		1.723	1.75	1.777	V
$I_{FB\_LK}$	FB leakage current (source or sink)	$V_{FB-RTN} = 1.75\text{ V}$			0.5	$\mu\text{A}$
$G_{BW}$	Small signal unity gain bandwidth		0.9	1.2		MHz
$A_{OL}$	Open loop voltage gain		70	90		dB
$V_{ZDC}$	0% duty-cycle threshold	$V_{COMP}$ falling until DRAIN switching stops	1.35	1.5	1.65	V
$I_{COMPH}$	COMP source current	$V_{FB} = V_{RTN}$ , $V_{COMP} = 3\text{ V}$	1			mA
$I_{COMPL}$	COMP sink current	$V_{FB} = V_{VB}$ , $V_{COMP} = 1.25\text{ V}$	2.1	6		mA
$V_{COMPH}$	COMP high voltage	$V_{FB} = V_{VB}$ , 15 k $\Omega$ from COMP to RTN	4		5	V
$V_{COMPL}$	COMP low voltage	$V_{FB} = V_{VB}$ , 15 k $\Omega$ from COMP to VB			1.1	V
	COMP to CS gain	$\Delta V_{CS} / \Delta V_{COMP}$ , $0\text{ V} < V_{CS} < 0.5\text{ V}$	0.475	0.5	0.525	V/V
<b>SOFT-START</b>						
$t_{SS}$	Soft-start period		8	16	24	ms
$t_{CD}$	Cool-down period		15	20	26	ms
<b>CURRENT SENSE (CS)</b>						
$V_{CSMAX}$	Maximum threshold voltage	$V_{FB} = V_{RTN}$ , $V_{CS}$ rising	0.5	0.55	0.6	V
$t_{OFFDEL\_ILM}$	Current limit turnoff delay	$V_{CS} = 0.65\text{ V}$	25	41	60	ns
$t_{OFFDEL\_PW}$	PWM comparator turnoff delay	$V_{CS} = 0.4\text{ V}$	25	41	60	
	Blanking delay	In addition to $t_{OFFDEL}$	56.5	75	93.5	ns

(1) The hysteresis tolerance tracks the rising threshold for a given device.

**Electrical Characteristics: DC-DC Controller Section (continued)**

Unless otherwise noted,  $V_{VDD} = 48\text{ V}$ ;  $R_{DEN} = 24.9\text{ k}\Omega$ ;  $R_{FRS} = 60.4\text{ k}\Omega$ ; CLS, AUX\_V, RSNS and DRAIN open; CS, AUX\_D, and GND connected to RTN; SRR connected to GND; SRF, FB and DTHR connected to VB;  $C_{VB} = 0.1\text{ }\mu\text{F}$ ;  $C_{CC} = 1\text{ }\mu\text{F}$ ;  $8.5\text{ V} \leq V_{VCC} \leq 16\text{ V}$ ;  $-40^\circ\text{C} \leq T_J \leq 125^\circ\text{C}$ . Positive currents are into pins unless otherwise noted. Typical values are at  $25^\circ\text{C}$ . [ $V_{VSS} = V_{RTN}$  and  $V_{VPD} = V_{VDD}$ ] or [ $V_{VSS} = V_{RTN} = V_{VPD}$ ], all voltages referred to  $V_{RTN}$  and  $V_{GND}$  unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
$V_{SLOPE}$	Internal slope compensation voltage	Peak voltage at maximum duty cycle, referred to CS	120	155	185	mV
$I_{SL\_EX}$	Peak slope compensation current	$V_{FB} = V_{RTN}$ , $I_{CS}$ at maximum duty cycle (ac component)	30	42	54	$\mu\text{A}$
	Bias current	DC component of CS current	-6.7	-5	-3.3	$\mu\text{A}$
<b>SWITCHING POWER FET (DRAIN, RSNS)</b>						
$BV_{DSS}$	Power FET break-down voltage		150			V
$R_{DS(ON)}$	Power FET on resistance			0.77	1.28	$\Omega$
$V_{SD}$	Source-to-drain diode forward voltage	$I_{RSNS} = 500\text{mA}$	0.6	1	1.1	V
<b>SECONDARY SIDE AUXILIARY POWER (AUX_D, AUX_V)</b>						
$V_{AUXEN}$	AUX_D threshold voltage	$V_{AUX\_D}$ rising	1.7	2	2.3	V
$V_{AUXH}$		Hysteresis <sup>(1)</sup>		0.15		V
$I_{pullup}$	AUX_D pullup current		70	100	130	$\mu\text{A}$
$V_{AVL}$	AUX_V output low voltage	$V_{AUX\_D} = V_{VB}$ , 5 K $\Omega$ from AUX_V to VB			50	mV
<b>THERMAL SHUTDOWN</b>						
	Turnoff temperature		145	159	165	$^\circ\text{C}$
	Hysteresis <sup>(2)</sup>			13		$^\circ\text{C}$

(2) These parameters are provided for reference only, and do not constitute part of TI's published device specifications for purposes of TI's product warranty.

## 7.6 Electrical Characteristics: PoE and Control

Unless otherwise noted,  $V_{VPD} = 48\text{ V}$ ;  $R_{DEN} = 24.9\text{ k}\Omega$ ;  $R_{FRS} = 60.4\text{ k}\Omega$ ; CLS, AUX\_V, RSNS and DRAIN open; CS, AUX\_D, and GND connected to RTN; SRR connected to GND; SRF, FB and DTHR connected to VB;  $C_{VB} = 0.1\text{ }\mu\text{F}$ ;  $C_{CC} = 1\text{ }\mu\text{F}$ ;  $-40^\circ\text{C} \leq T_j \leq 125^\circ\text{C}$ . Positive currents are into pins unless otherwise noted. Typical values are at  $25^\circ\text{C}$ .

Unless otherwise noted,  $V_{VPD} = V_{VDD}$ ,  $V_{VCC} = V_{RTN}$ . All voltages referred to  $V_{VSS}$  unless otherwise noted.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>PD DETECTION (DEN)</b>						
	Detection bias current	DEN open, $V_{VPD} = 10\text{ V}$ , Measure $I_{VPD} + I_{VDD} + I_{DEN} + I_{RTN}$	3.5	8.3	13.9	$\mu\text{A}$
$I_{lkg}$	DEN leakage current	$V_{DEN} = V_{VPD} = 57\text{ V}$ , Measure $I_{DEN}$		0.1	5	$\mu\text{A}$
	Detection current	Measure $I_{VPD} + I_{VDD} + I_{DEN} + I_{RTN}$ , $V_{VPD} = 1.4\text{ V}$	55.5	56.3	60	$\mu\text{A}$
		Measure $I_{VPD} + I_{VDD} + I_{DEN} + I_{RTN}$ , $V_{VPD} = 10\text{ V}$	400	407	414.5	$\mu\text{A}$
$V_{PD\_DIS}$	Hotswap disable threshold		3	4	5	V
<b>PD CLASSIFICATION (CLS)</b>						
$I_{CLS}$	Classification current	$R_{CLS} = 649\text{ }\Omega$	1.8	2.14	2.4	mA
		$R_{CLS} = 121\text{ }\Omega$	9.9	10.6	11.3	
		$R_{CLS} = 68.1\text{ }\Omega$	17.6	18.6	19.4	
		$R_{CLS} = 45.3\text{ }\Omega$	26.5	27.9	29.3	
$V_{CL\_ON}$	Classification regulator lower threshold	Regulator turns on, $V_{VPD}$ rising	10.7	12.1	13	V
$V_{CL\_HYS}$		Hysteresis <sup>(1)</sup>	0.6	1.1	1.55	V
$V_{CU\_OFF}$	Classification regulator upper threshold	Regulator turns off, $V_{VPD}$ rising	21	22	23	V
$V_{CU\_HYS}$		Hysteresis <sup>(1)</sup>	0.5	0.77	1	V
$I_{lkg}$	Leakage current	$V_{VPD} = 57\text{ V}$ , $V_{CLS} = 0\text{ V}$ , $V_{DEN} = V_{VSS}$ , Measure $I_{CLS}$			1	$\mu\text{A}$
<b>RTN (PASS DEVICE)</b>						
	ON-resistance		0.36	0.68		$\Omega$
	Current limit	$V_{RTN} = 1.5\text{ V}$ , pulsed measurement	405	550	800	mA
	Inrush current limit	$V_{RTN} = 2\text{ V}$ , $V_{VPD}$ : $0\text{ V} \rightarrow 48\text{ V}$ , pulsed measurement	100	140	220	mA
	Foldback voltage threshold	$V_{RTN}$ rising	11	12.3	13.6	V
	Foldback deglitch time	$V_{RTN}$ rising to when current limit changes to inrush current limit	150	387	600	$\mu\text{s}$
$I_{lkg}$	Leakage current	$V_{VPD} = V_{RTN} = 100\text{ V}$ , $V_{DEN} = V_{VSS}$			40	$\mu\text{A}$
<b>PD INPUT SUPPLY (VPD, VDD)</b>						
$UVLO\_R$	Undervoltage lockout threshold	$V_{VPD}$ rising	34.7	35.5	36.7	V
$UVLO\_H$		Hysteresis <sup>(1)</sup>	4.1	4.5	4.7	V
$I_{VPD\_VDD}$	Operating current	VCC open, $40\text{ V} \leq V_{VPD} = V_{VDD} \leq 57\text{ V}$ , Startup completed, Measure $I_{VPD} + I_{VDD}$	300	580		$\mu\text{A}$
	Off-state current	RTN, GND and VCC open, $V_{VPD} = 30\text{ V}$ , Measure $I_{VPD}$		330		
<b>THERMAL SHUTDOWN</b>						
	Turnoff temperature		145	159	165	$^\circ\text{C}$
	Hysteresis <sup>(2)</sup>			13		$^\circ\text{C}$

(1) The hysteresis tolerance tracks the rising threshold for a given device.

(2) These parameters are provided for reference only.

## 8 Detailed Description

### 8.1 Overview

The TPS23755 device is a 24-pin integrated circuit that contains all of the features needed to implement an IEEE802.3at Type-1 powered device (PD), combined with a fully integrated 150-V switching power FET and a current-mode DC-DC controller optimized for flyback switching regulator designs using primary side control. The TPS23755 applies to single-output flyback converter applications where a secondary side diode rectifier is used.

Basic PoE PD functionality supported includes detection, hardware classification, and inrush current limit during startup. DC-DC converter features include startup function and current mode control operation. The TPS23755 device integrates a low 0.36- $\Omega$  internal switch to support Type-1 applications.

The TPS23755 features secondary auxiliary power detect (AUX\_D) capability, providing priority for a secondary side power adapter, while ensuring smooth transition (via AUX\_V) to and from the PoE power input.

The TPS23755 device contains several protection features such as  $f$ , current limit foldback, and a robust 100-V internal return switch.

### 8.3 Feature Description

See [Figure 38](#) for component reference designators ( $R_{CS}$  for example), and [Electrical Characteristics: DC-DC Controller Section](#) for values denoted by reference ( $V_{CSMAX}$  for example). Electrical Characteristic values take precedence over any numerical values used in the following sections.

#### 8.3.1 CLS Classification

An external resistor ( $R_{CLS}$  in [Figure 38](#)) connected between the CLS pin and VSS provides a classification signature to the PSE. The controller places a voltage of approximately 1.25 V across the external resistor whenever the voltage differential between VPD and VSS lies from about 11 V to 22 V. The current drawn by this resistor, combined with the internal current drain of the controller and any leakage through the internal pass MOSFET, creates the classification current. [Table 2](#) lists the external resistor values required for each of the PD power ranges defined by IEEE802.3at. The maximum average power drawn by the PD, plus the power supplied to the downstream load, should not exceed the maximum power indicated in [Table 2](#). The TPS23755 supports class 0 – 3 power levels.

**Table 2. Class Resistor Selection**

CLASS	POWER AT PD PI		RESISTOR ( $\Omega$ )
	MINIMUM (W)	MAXIMUM (W)	
0	0.44	12.95	649
1	0.44	3.84	121
2	3.84	6.49	68.1
3	6.49	12.95	45.3

#### 8.3.2 DEN Detection and Enable

DEN pin implements two separate functions. A resistor ( $R_{DEN}$  in [Figure 38](#)) connected between VPD and DEN generates a detection signature whenever the voltage differential between VPD and VSS lies from approximately 1.4 to 11 V. Beyond this range, the controller disconnects this resistor to save power. The IEEE 802.3at standard specifies a detection signature resistance,  $R_{DEN}$  from 23.75 k $\Omega$  to 26.25 k $\Omega$ , or 25 k $\Omega \pm 5\%$ . TI recommends a resistor of 24.9 k $\Omega \pm 1\%$  for  $R_{DEN}$ .

Pulling DEN to VSS during powered operation causes the internal hotswap MOSFET and class regulator to turn off. If the resistance connected between VDD and DEN is divided into two roughly equal portions, then the application circuit can disable the PD by grounding the tap point between the two resistances, while simultaneously spoiling the detection signature which prevents the PD from properly re-detecting.

#### 8.3.3 Internal Pass MOSFET

RTN pin provides the negative power return path for the load. It is internally connected to the drain of the PoE hotswap MOSFET, and the DC-DC controller return. RTN must be treated as a local reference plane (ground plane) for the DC-DC controller and converter primary to maintain signal integrity.

Once  $V_{VPD}$  exceeds the UVLO threshold, the internal pass MOSFET pulls RTN to VSS. Inrush limiting prevents the RTN current from exceeding a nominal value of about 140 mA until the bulk capacitance ( $C_{BULK}$  in [Figure 38](#)) is fully charged. Inrush ends when the RTN current drops below about 125 mA. The RTN current is subsequently limited to about 0.45 A

If RTN ever exceeds about 12.3 V for longer than 400  $\mu$ s, then the PD returns to inrush limiting.

#### 8.3.4 DC-DC Controller Features

The TPS23755 device DC-DC controller implements a typical current-mode control as shown in [Functional Block Diagram](#). Features include oscillator, overcurrent and PWM comparators, current-sense blanker, soft start, gate driver and switching power FET. In addition, an internal current-compensation ramp generator, frequency synchronization logic, built-in frequency dithering functionality, thermal shutdown, and start-up current source with control are provided.

The TPS23755 is optimized for isolated converters, and it includes an internal error amplifier. The voltage feedback is from the bias winding. The COMP output of the error amplifier is directly fed to a 2:1 internal resistor divider and an offset of  $V_{ZDC}/2$  (approximately 0.75 V) which defines a current-demand control for the pulse width modulator (PWM). A  $V_{COMP}$  below  $V_{ZDC}$  stops converter switching, while voltages above ( $V_{ZDC} + 2 \times (V_{CSMAX} + V_{SLOPE})$ ) does not increase the requested peak current in the switching MOSFET.

The internal start-up current source and control logic implement a bootstrap-type startup. The startup current source charges  $C_{CC}$  from VDD and maintain its voltage when the converter is disabled or during the soft-start period, while operational power must come from a converter (bias winding) output.

The bootstrap source provides reliable start-up from widely varying input voltages, and eliminates the continual power loss of external resistors.

The peak current limit does not have duty cycle dependency unless  $R_S$  is used as shown in [Figure 28](#) to increase slope compensation. This makes it easier to design the current limit to a fixed value.

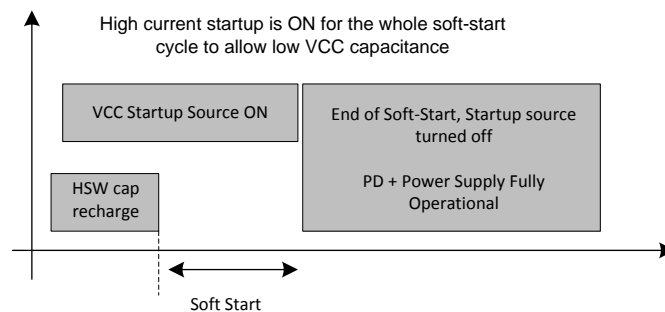

The DC-DC controller has an OTSD that can be triggered by heat sources including the power switching FET and GATE driver. The controller OTSD turns off the switching FET and resets the soft-start generator.

#### 8.3.4.1 VCC, VB and Advanced PWM Startup

The VCC pin connects to the auxiliary bias supply for the DC-DC controller. The switching MOSFET gate driver draws current directly from the VB pin, which is the output of an internal 5V regulator fed from VCC. A startup current source from VDD to VCC implements the converter bootstrap startup. VCC must receive power from an auxiliary source, such as an auxiliary winding on the flyback transformer, to sustain normal operation after startup.

The startup current source is turned on during the inrush phase, charging  $C_{CC}$  and maintaining its voltage, and it is turned off only after the DC-DC soft-start cycle has been completed, which occurs when the DC-DC converter has ramped up its output voltage, as shown in [Figure 27](#). Internal loading on VCC and VB is initially minimal while  $C_{CC}$  charges, to allow the converter to start. Due to the high current capability of the startup source, the recommended capacitance at VCC is relatively small, typically 1  $\mu$ F in most applications.

Once  $V_{VCC}$  falls below its UVLO threshold, the converter shuts off and the startup current source is turned back on, initiating a new PWM startup cycle.

**Figure 27. Advanced Startup**

#### 8.3.4.2 CS, Current Slope Compensation and blanking

The current-sense input for the DC-DC converter should be connected to the high side of the current-sense resistor of the switching MOSFET. The current-limit threshold,  $V_{CSMAX}$ , defines the voltage on CS above which the switching FET ON-time is terminated regardless of the voltage on COMP output.

Routing between the current-sense resistor and the CS pin must be short to minimize cross-talk from noisy traces such as DRAIN and CP, and to a lower degree to SRR and SRF.

Current-mode control requires addition of a compensation ramp to the sensed inductor (flyback transformer) current for stability at duty cycles near and over 50%. The TPS23755 has a maximum duty cycle limit of 78.5%, permitting the design of wide input-range flyback converters with a lower voltage stress on the output rectifiers. While the maximum duty cycle is 78.5%, converters may be designed that run at duty cycles well below this for a narrower, 36-V to 57-V range. The TPS23755 provides a fixed internal compensation ramp that suffices for most applications.  $R_S$  (see [Figure 28](#)) may be used if the internally provided slope compensation is not enough. It works with ramp current ( $I_{PK} = I_{SL-EX}$ , approximately 40  $\mu\text{A}$ ) that flows out of the CS pin when the MOSFET is on. The  $I_{PK}$  specification does not include the approximately 5- $\mu\text{A}$  fixed current that flows out of the CS pin.

Most current-mode control papers and application notes define the slope values in terms of  $V_{pp}/T_S$  (peak ramp voltage / switching period); however, [Electrical Characteristics: DC-DC Controller Section](#) specifies the slope peak ( $V_{SLOPE}$ ) based on the maximum duty cycle. Assuming that the desired slope,  $V_{SLOPE-D}$  (in mV/period), is based on the full period, compute  $R_S$  per [Equation 1](#) where  $V_{SLOPE}$ ,  $D_{MAX}$ , and  $I_{SL-EX}$  are from [Electrical Characteristics: DC-DC Controller Section](#) with voltages in mV, current in  $\mu\text{A}$ , and the duty cycle is unitless (for example,  $D_{MAX} = 0.78$ ).

$$R_S(\Omega) = \frac{[V_{SLOPE\_D}(\text{mV}) - (V_{SLOPE}(\text{mV})/D_{MAX})]}{I_{SL-EX}(\mu\text{A})/D_{MAX}} \times 1000 \quad (1)$$

**Figure 28. Additional Slope Compensation**

Blanking provides an interval between the FET gate drive going high and the current comparator on CS actively monitoring the input. This delay allows the normal turnon current transient (spike) to subside before the comparator is active, preventing undesired short duty cycles and premature current limiting.

The TPS23755 blanker timing is precise enough that the traditional R-C filters on CS can be eliminated. This avoids current-sense waveform distortion, which tends to get worse at light output loads. There may be some situations or designers that prefer an R-C approach, for example if the presence of  $R_S$  causes increased noise, due to adjacent noisy signals, to appear at CS pin. The TPS23755 provides a pulldown on CS (approximately 400  $\Omega$ ) during the GATE OFF-time to improve sensing when an R-C filter must be used, by reducing cycle-to-cycle carry-over voltage on  $C_S$ .

### 8.3.4.3 COMP, FB, CP and Opto-less Feedback

The TPS23755 DC-DC controller implements current-mode control, using a voltage control loop error amplifier (pins FB and COMP) to define the input reference voltage of the current mode control comparator which determines the switching MOSFET peak current. Loop compensation components are connected between COMP and FB.

$V_{COMP}$  below  $V_{ZDC}$  causes the converter to stop switching. The maximum (peak) current is requested at approximately  $(V_{ZDC} + 2 \times (V_{CSMAX} + V_{SLOPE}))$ . The AC gain from COMP to the PWM comparator is 0.5.

The TPS23755 DC-DC controller can operate with feedback from an auxiliary winding of the flyback power transformer, eliminating the need for external shunt regulator and optocoupler. It also operates with continuously connected feedback, enabling better optimization of the power supply, and resulting in significantly lower noise sensitivity.

The TPS23755 applies to single-output flyback converter applications where a secondary side diode rectifier is used. In typical 12 V output application and when combined with a correctly designed power transformer,  $\pm 5\%$  load regulation over a wide (5% to 100%) output current range can be achieved.

### 8.3.4.4 FRS Frequency Setting and Synchronization

The FRS pin programs the (free-running) oscillator frequency, and may also be used to synchronize the TPS23755 converter to a higher frequency. The internal oscillator sets the maximum duty cycle and controls the current-compensation ramp circuit, making the ramp height independent of frequency.  $R_{FRS}$  must be selected per Equation 2.

$$R_{FRS} \text{ (k}\Omega\text{)} = \frac{15000}{f_{SW} \text{ (kHz)}} \quad (2)$$

The TPS23755 may be synchronized to an external clock to eliminate beat frequencies from a sampled system, or to place emission spectrum away from an RF input frequency. Synchronization may be accomplished by applying a short pulse ( $> 35$  ns) of magnitude  $V_{SYNC}$  to FRS as shown in Figure 29.  $R_{FRS}$  must be chosen so that the maximum free-running frequency is just below the desired synchronization frequency. The synchronization pulse terminates the potential ON-time period, and the OFF-time period does not begin until the pulse terminates. A short pulse is preferred to avoid reducing the potential ON-time.

Figure 29 shows examples of nonisolated and transformer-coupled synchronization circuits.  $R_T$  reduces noise susceptibility for the isolation transformer implementation. The FRS node must be protected from noise because it is high impedance.

**Figure 29. Synchronization**

### 8.3.4.5 Frequency Dithering for Spread Spectrum Applications

The international standard CISPR 22 (and adopted versions) is often used as a requirement for conducted emissions. Ethernet cables are covered as a telecommunication port under section 5.2 for conducted emissions. Meeting EMI requirements is often a challenge, with the lower limits of Class B being especially hard. Circuit board layout, filtering, and snubbing various nodes in the power circuit are the first layer of control techniques. A more detailed discussion of EMI control is presented in *Practical Guidelines to Designing an EMI Compliant PoE Powered Device With Isolated Flyback*, SLUA469. Additionally, IEEE 802.3at sections 33.3 and 33.4 have requirements for noise injected onto the Ethernet cable based on compatibility with data transmission.

A technique referred to as frequency dithering can also be used to provide additional EMI measurement reduction. The switching frequency is modulated to spread the narrowband individual harmonics across a wider bandwidth, thus lowering peak measurements.

Frequency dithering is a built-in feature of the TPS23755. The oscillator frequency can be dithered by connecting a capacitor from DTHR to RTN and a resistor from DTHR to FRS. An external capacitor,  $C_{DTR}$  (Figure 38), is selected to define the modulation frequency  $f_m$ . This capacitor is being continuously charged and discharged between slightly less than 0.5 V and slightly above 1.5 V by a current source/sink equivalent to approximately 3x the current through FRS pin.  $C_{DTR}$  value is defined according to:

$$C_{DTR} = \frac{3/R_{FRS} \text{ (}\Omega\text{)}}{2.052 \times f_m \text{ (Hz)}} \quad (3)$$

$f_m$  should always be higher than 9 kHz, which is the resolution bandwidth applied during conducted emission measurement. Typically,  $f_m$  should be set to around 11 kHz to account for component variations.

The resistor  $R_{DTR}$  is used to determine  $\Delta f$ , which is the amount of dithering, and its value is determined according to:

$$R_{DTR} (\Omega) = \frac{0.513 \times R_{FRS} (\Omega)}{\%DTHR} \quad (4)$$

For example, a 13.2% dithering with a nominal switching frequency of 250 kHz results in frequency variation of  $\pm 33$  kHz.

#### 8.3.4.6 SST and Soft-Start of the Switcher

Converters require a soft-start on the voltage error amplifier to prevent output overshoot on startup. In PoE applications, the PD also needs soft-start to limit its input current at turnon below the limit allocated by the power source equipment (PSE).

The TPS23755 provides primary side closed loop controlled soft-start, which applies a slowly rising ramp voltage to a second control input of the error amplifier. The lower of the reference input and soft-start ramps controls the error amplifier, allowing the output voltage to rise in a smooth monotonic fashion.

The soft-start period of the TPS23755 is internally set to a nominal value of 16 ms.

#### 8.3.4.7 AUX\_V, AUX\_D and Secondary Adapter Or'ing

The TPS23755's unique auxiliary power detect capability provides priority for a secondary side power adapter, while ensuring smooth transition to and from the PoE power. This can be applied for example in applications where the auxiliary power is the main power, while the PoE input acts as the backup power. The auxiliary voltage is "Or'd" directly at the output of flyback transformer, on secondary side. See [Figure 30](#) below where the output voltage is nominally 12 V.

When the auxiliary is present, a signal (AUX\_D) tells the PD PWM to lower its output voltage slightly below the auxiliary voltage to ensure the auxiliary has priority to power the main output. When the auxiliary power goes away, the DC-DC converter increases back its output voltage, to ensure seamless transition. One significant advantage of this approach is that the efficiency of the PoE-powered flyback power stage can be optimized independently of the need for seamless transition. The adjustability of the lower voltage level allows the use of highly inaccurate auxiliary voltage sources. Such feature eases the thermal design, in particular when secondary diode rectification is used, since when PoE powered, the flyback stage can deliver power at a higher output voltage, and hence at a lower output current.

In [Figure 30](#) below,  $R_{OUT1}$  ensures that the PSE maintains power while the auxiliary is present, ensuring there will be no power interruption when the auxiliary power is removed.

The lower voltage level is programmable with the  $R_{AUX}$  resistor, which impacts the feedback network division ratio. Note however that the flyback power transformer design and resistor selection must be such that  $V_{VCC}$  will remain above nominally 6.1 V ( $V_{C_{UVF}}$ ) while the auxiliary power is present.

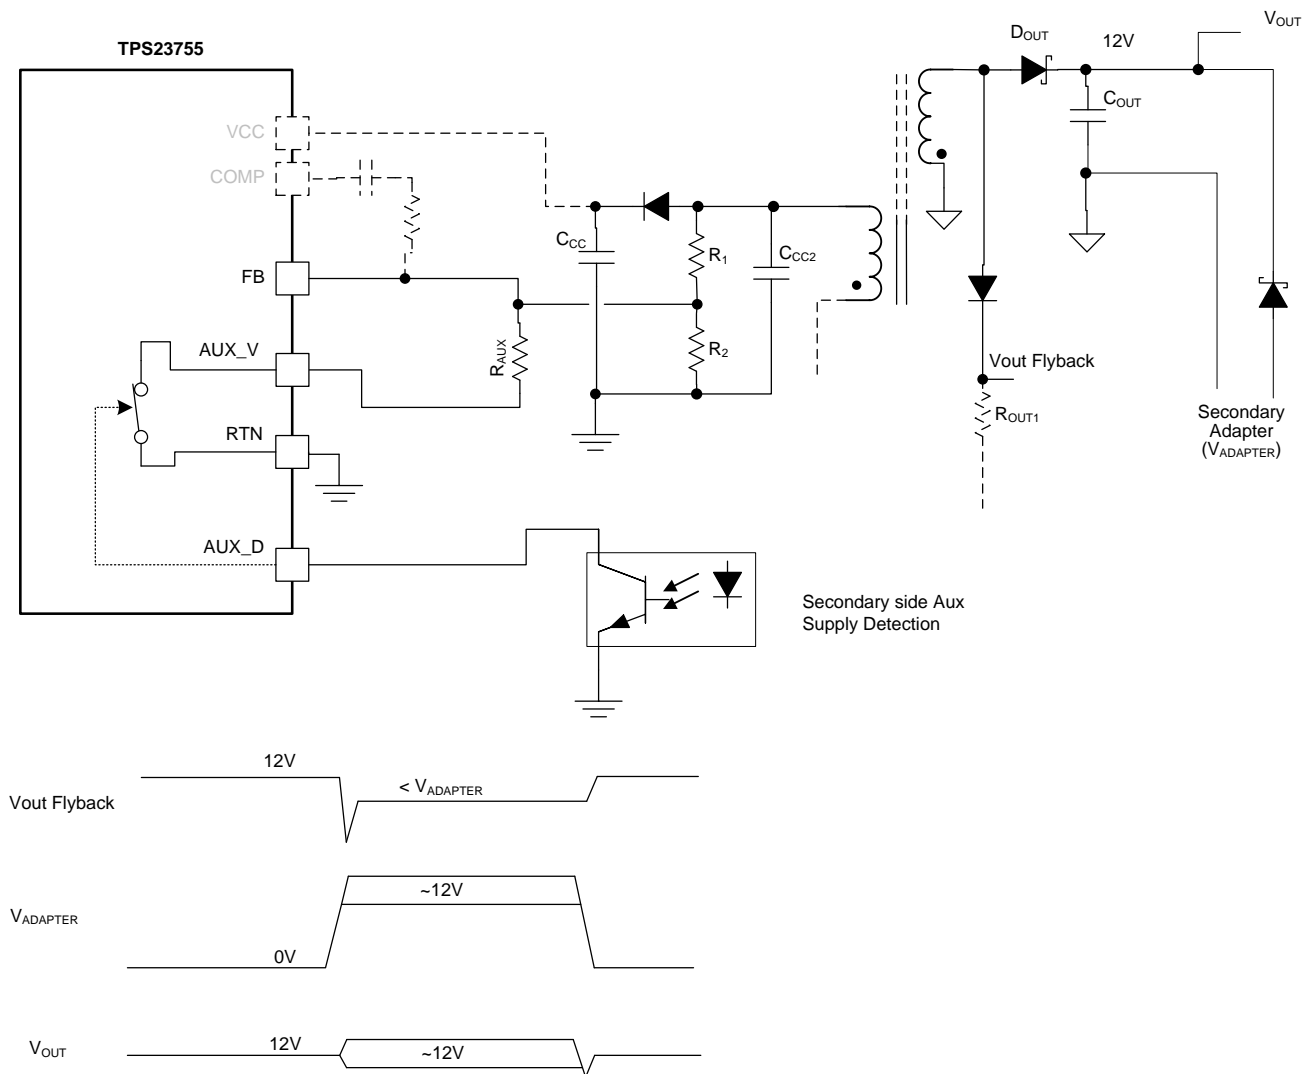

Figure 30. Secondary Side Priority Control with Smooth Transition

### 8.3.5 Internal Switching FET - DRAIN, RSNS, SRF and SRR

The DRAIN and RSNS provide connection to the drain and source of the integrated switching power FET. RSNS pin is a high current pin and it must have a short connection to the current sense resistor which other end is directly tied to a plane referenced to the GND pin. Current sensing is done with CS pin, which should be connected directly to the high side of the current sense resistor.

The internal FET gate driver is powered from VB voltage rail and the return path is through the GND pin. SRF and SRR pins provide slew rate control of the switching FET. The gate sourcing current is drawn through the SRF pin which is tied to VB pin through a resistor (0-100 Ω). The gate sinking current circulates through the SRR pin which is externally tied to the GND pin either via a low-value resistor (0-15 Ω) or a direct connection.

### 8.3.6 VPD Supply Voltage

VPD pin connects to the positive side of the input supply. It provides operating power to the PD controller and allows monitoring of the input line voltage. If V<sub>VPD</sub> falls below its UVLO threshold and goes back above it, or if a thermal shutdown resumes while V<sub>VPD</sub> is already above its UVLO threshold, the TPS23755 returns to inrush limiting.

### 8.3.7 VDD Supply Voltage

VDD connects to the source of DC-DC converter startup current. It is connected to VPD for most applications. It may also be isolated by a diode from VPD to support some PoE priority operation.

### 8.3.8 GND

GND is the power ground used by the flyback power FET gate driver and CP pin. Connect to the RTN plane. VB bypassing capacitor should be directly connected to the GND pin.

### 8.3.9 VSS

VSS is the PoE input-power return side. It is the reference for the PoE interface circuits, and has a current-limited hotswap switch that connects it to RTN. VSS is clamped to a diode drop above RTN by the hotswap switch. The exposed thermal PAD must be connected to this pin to ensure proper operation.

### 8.3.10 Exposed Thermal PAD

The exposed thermal PAD is internally connected to VSS pin. It should be tied to a large VSS copper area on the PCB to provide a low resistance thermal path to the circuit board. TI recommends maintaining a clearance of 0.025" between VSS and high-voltage signals such as VPD and VDD.

## 8.4 Device Functional Modes

### 8.4.1 PoE Overview

The following text is intended as an aid in understanding the operation of the TPS23755, but it is not a substitute for the actual IEEE 802.3at standard. The IEEE 802.3at standard is an update to IEEE 802.3-2008 clause 33 (PoE), adding high-power options and enhanced classification.

Generally speaking, a device compliant to IEEE 802.3-2008 is referred to as a Type 1 device, and devices with high power or enhanced classification is referred to as Type 2 devices. The TPS23755 is intended to power Type 1 devices (up to 13 W), and is fully compliant to IEEE 802.3at for hardware classes 0 - 3. Standards change and must always be referenced when making design decisions.

The IEEE 802.3at standard defines a method of safely powering a PD (powered device) over a cable, and then removing power if a PD is disconnected. The process proceeds through an idle state and three operational states of detection, classification, and operation. The PSE leaves the cable unpowered (idle state) while it periodically looks to see if something has been plugged in; this is referred to as detection. The low power levels used during detection are unlikely to damage devices not designed for PoE. If a valid PD signature is present, the PSE may inquire how much power the PD requires; this is referred to as (hardware) classification. Only Type 2 PSEs are required to do hardware classification. The PD may return the default 13-W current-encoded class, or one of four other choices. The PSE may then power the PD if it has adequate capacity. Once started, the PD must present the maintain power signature (MPS) to assure the PSE that it is still present. The PSE monitors its output for a valid MPS, and turns the port off if it loses the MPS. Loss of the MPS returns the PSE to the idle state. Figure 31 shows the operational states as a function of PD input voltage.

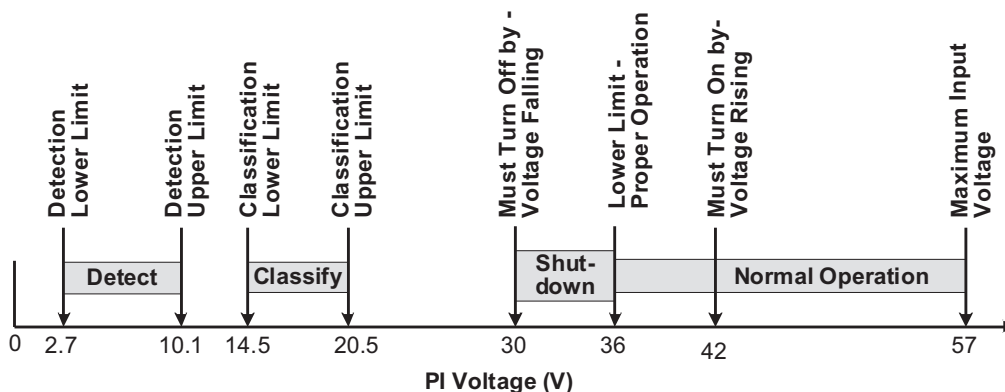

Figure 31. Operational States

## Device Functional Modes (continued)

The PD input is typically an RJ-45 eight-lead connector which is referred to as the power interface (PI). PD input requirements differ from PSE output requirements to account for voltage drops in the cable and operating margin. The IEEE 802.3at standard uses a cable resistance of 20 Ω for Type 1 devices to derive the voltage limits at the PD based on the PSE output voltage requirements. Although the standard specifies an output power of 15.4 W at the PSE, only 13 W is available at the PI due to the worst-case power loss in the cable. The PSE can apply voltage either between the RX and TX pairs (pins 1–2 and 3–6 for 10baseT or 100baseT), or between the two spare pairs (4–5 and 7–8). Power application to the same pin combinations in 1000baseT systems is recognized in IEEE 802.3at. 1000baseT systems can handle data on all pairs, eliminating the spare pair terminology. The PSE may only apply voltage to one set of pairs at a time. The PD uses input diode bridges to accept power from any of the possible PSE configurations. The voltage drops associated with the input bridges create a difference between the standard limits at the PI and the TPS23755 specifications.

The PSE is permitted to disconnect a PD if it draws more than its maximum class power over a one second interval. A Type 1 PSE compliant to IEEE 802.3at is required to limit current to between 400 mA and 450 mA during powered operation, and it must disconnect the PD if it draws this current for more than 75 ms. Class 0 and 3 PDs may draw up to 400-mA peak currents for up to 50 ms. The PSE may set lower output current limits based on the declared power requirements of the PD.

### 8.4.2 Threshold Voltages

The TPS23755 has a number of internal comparators with hysteresis for stable switching between the various states as shown in Figure 31. Figure 32 relates the parameters in *Electrical Characteristics: DC-DC Controller Section* and *Electrical Characteristics: PoE and Control* to the PoE states. The mode labeled idle between classification and operation implies that the DEN, CLS, and RTN pins are all high impedance.

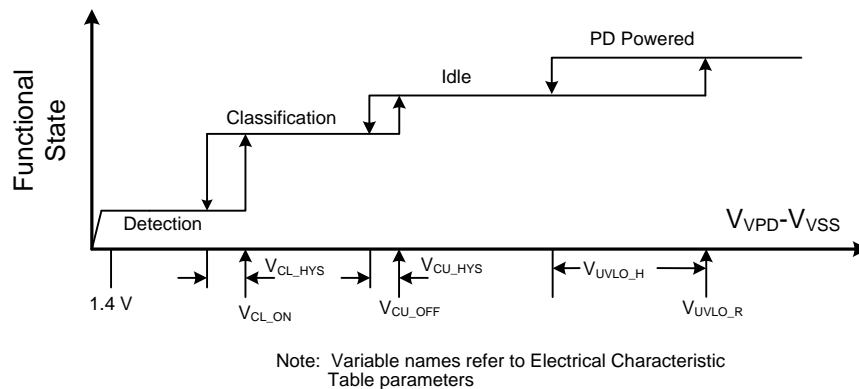

Figure 32. Threshold Voltages

### 8.4.3 PoE Start-Up Sequence

The waveforms of Figure 33 demonstrate detection, classification, and start-up from a Type 1 PSE. The key waveforms shown are  $V_{VPD-VSS}$ ,  $V_{RTN-VSS}$ , and  $I_{PI}$ . IEEE 802.3at requires a minimum of two detection levels; however, four levels are shown in this example. Four levels guard against misdetection of a device when plugged in during the detection sequence.

Device Functional Modes (continued)

Figure 33. PoE Start-Up Sequence

8.4.4 Detection

The TPS23755 is in detection mode whenever  $V_{VPD-VSS}$  is below the lower classification threshold. When the input voltage rises above  $V_{CL\_ON}$ , the DEN pin goes to an open-drain condition to conserve power. While in detection, RTN is high impedance, almost all the internal circuits are disabled, and the DEN pin is pulled to  $V_{SS}$ . An  $R_{DEN}$  of 24.9 k $\Omega$  (1%), presents the correct signature. It may be a small, low-power resistor because it only sees a stress of about 5 mW. A valid PD detection signature is an incremental resistance between 23.75 k $\Omega$  and 26.25 k $\Omega$  at the PI.

The detection resistance seen by the PSE at the PI is the result of the input bridge resistance in series with the parallel combination of  $R_{DEN}$  and the TPS23755 bias loading. The incremental resistance of the input diode bridge may be hundreds of ohms at the very low currents drawn when 2.7 V is applied to the PI. The input bridge resistance is partially cancelled by the effective resistance of the TPS23755 during detection.

8.4.5 Hardware Classification

Hardware classification allows a PSE to determine the power requirements of a PD before starting, and helps with power management once power is applied. The maximum power entries in Table 2 determine the class the PD must advertise. A Type 1 PD may not advertise Class 4. The PSE may disconnect a PD if it draws more than its stated Class power. The standard permits the PD to draw limited current peaks; however, the average power requirement always applies.

Voltage from 14.5 V to 20.5 V is applied to the PD for up to 75 ms during hardware classification. A fixed output voltage is sourced by the CLS pin, causing a fixed current to be drawn from VPD through  $R_{CLS}$ . The total current drawn from the PSE during classification is the sum of bias and  $R_{CLS}$  currents. PD current is measured and decoded by the PSE to determine which of the five available classes is advertised (see Table 2). The TPS23755 disables classification above  $V_{CU\_OFF}$  to avoid excessive power dissipation. CLS voltage is turned off during PD thermal limit or when DEN is active. The CLS output is inherently current-limited, but should not be shorted to VSS for long periods of time.

## Device Functional Modes (continued)

### 8.4.6 Maintain Power Signature (MPS)

The MPS is an electrical signature presented by the PD to assure the PSE that it is still present after operating voltage is applied. A valid MPS consists of a minimum DC current of 10 mA (at a duty cycle of at least 75 ms on every 225 ms) and an AC impedance lower than 26.25 k $\Omega$  in parallel with 0.05  $\mu$ F. The AC impedance is usually accomplished by the minimum  $C_{BULK}$  requirement of 5  $\mu$ F. When DEN is used to force the hotswap switch off, the DC MPS is not met. A PSE that monitors the DC MPS will remove power from the PD when this occurs. A PSE that monitors only the AC MPS may remove power from the PD.

### 8.4.7 Start-Up and Converter Operation

The internal PoE undervoltage lockout (UVLO) circuit holds the hotswap switch off before the PSE provides full voltage to the PD. This prevents the converter circuits from loading the PoE input during detection and classification. The converter circuits discharge  $C_{DD}$ ,  $C_{CC}$ , and  $C_{VB}$  while the PD is unpowered. Thus  $V_{VDD-RTN}$  will be a small voltage until just after full voltage is applied to the PD, as seen in [Figure 33](#).

The PSE drives the PD input voltage to the operating range once it has decided to power up the PD. When  $V_{PD}$  rises above the UVLO turnon threshold ( $V_{UVLO-R}$ , approximately 35.5 V) with RTN high, the TPS23755 enables the hotswap MOSFET with an approximately 140-mA (inrush) current limit. See the waveforms of [Figure 34](#) for an example. Converter switching is disabled while  $C_{DD}$  charges and  $V_{RTN}$  falls from  $V_{VDD}$  to nearly  $V_{VSS}$ ; however, the converter start-up circuit is allowed to charge  $C_{CC}$ . Once the inrush current falls about 10% below the inrush current limit, the PD control switches to the operational level (approximately 450 mA) and converter switching is permitted.

Converter switching is allowed if the PD is not in inrush current limit and the VCC under-voltage lockout ( $V_{CUVR}$ ) circuit permits it. Continuing the start-up sequence shown in [Figure 34](#),  $V_{VCC}$  rises as the start-up current source charges  $C_{CC}$  and the converter switching is inhibited by the status of the VCC UVLO. The VB regulator powers the internal converter circuits as  $V_{VCC}$  rises.

Once  $V_{VCC}$  goes above its UVLO (nominally 8.25 V), the converter switching is enabled following the closed loop controlled soft-start sequence. Note that the startup current source capability is such that it can fully maintain  $V_{VCC}$  during the converter soft-start without requiring any significant  $C_{CC}$  capacitance, in 48 V input applications. At the end of the soft-start period, the startup current source is turned off.  $V_{VCC}$  falls as it powers the internal circuits including the switching MOSFET gate. If the converter control-bias output rises to support  $V_{VCC}$  before it falls to  $V_{CUVF}$  (nominally 6.1 V), a successful start-up occurs. [Figure 34](#) shows a small droop in  $V_{VCC}$  while the output voltage rises smoothly and a successful start-up occurs.

Device Functional Modes (continued)

Figure 34. Power Up and Start

The converter shuts off when  $V_{VCC}$  falls below its lower UVLO. This can happen when power is removed from the PD, or during a fault on a converter output rail. When one output is shorted, all the output voltages fall including the one that powers VCC. The control circuit discharges VCC until it hits the lower UVLO and turns off. A restart initiates if the converter turns off and there is sufficient VDD voltage. This type of operation is sometimes referred to as *hiccup mode*, which when combined with the soft-start provides robust output short protection by providing time-average heating reduction of the output rectifier.

Figure 35 illustrates the situation when there is severe overload at the main output which causes VCC hiccup. After VCC went below its UVLO due to the overload, the startup source is turned back on. Then, a new soft-start cycle is reinitiated, introducing a short pause before the output voltage is ramped up.

**Device Functional Modes (continued)**

**Figure 35. Restart Following Severe Overload at Main Output of Flyback DC-DC Converter**

If  $V_{VPD-VSS}$  drops below the lower PoE UVLO (UVLO\_R – UVLO\_H, approximately 31 V), the hotswap MOSFET is turned off, but the converter still runs. The converter stops if  $V_{VCC}$  falls below the  $V_{CUVF}$  (nominally 6.1 V), the hotswap is in inrush current limit, the SST pin is pulled to ground,  $V_{VDD-RTN}$  falls below typically 7.7 V (approximately 0.75 V hysteresis) or the converter is in thermal shutdown.

#### 8.4.8 PD Self-Protection

The PD section has the following self-protection functions.

- Hotswap switch current limit
- Hotswap switch foldback
- Hotswap thermal protection

The internal hotswap MOSFET is protected against output faults with a current limit and deglitched foldback. The PSE output cannot be relied on to protect the PD MOSFET against transient conditions, requiring the PD to provide fault protection. High stress conditions include converter output shorts, shorts from VDD to RTN, or transients on the input line. An overload on the pass MOSFET engages the current limit, with  $V_{RTN-VSS}$  rising as a result. If  $V_{RTN}$  rises above approximately 12.3 V for longer than approximately 400  $\mu$ s, the current limit reverts to the inrush limit, and turns the converter off. The 400- $\mu$ s deglitch feature prevents momentary transients from

**Device Functional Modes (continued)**

causing a PD reset, provided that recovery lies within the bounds of the hotswap and PSE protection. [Figure 36](#) shows an example of recovery from a 15-V PSE rising voltage step. The hotswap MOSFET goes into current limit, overshooting to a relatively low current, recovers to 420-mA, full-current limit, and charges the input capacitor while the converter continues to run. The MOSFET did not go into foldback because  $V_{RTN-VSS}$  was below 12 V after the 400- $\mu$ s deglitch.

**Figure 36. Response to PSE Step Voltage**

The PD control has a thermal sensor that protects the internal hotswap MOSFET. Conditions like start-up or operation into a VPD to RTN short cause high power dissipation in the MOSFET. An overtemperature shutdown (OTSD) turns off the hotswap MOSFET and class regulator, which are restarted after the device cools. The PD restarts in inrush current limit when exiting from a PD overtemperature event.

Pulling DEN to VSS during powered operation causes the internal hotswap MOSFET to turn off. This feature allows a PD with secondary-side adapter ORing to achieve adapter priority. Take care with synchronous converter topologies that can deliver power in both directions.

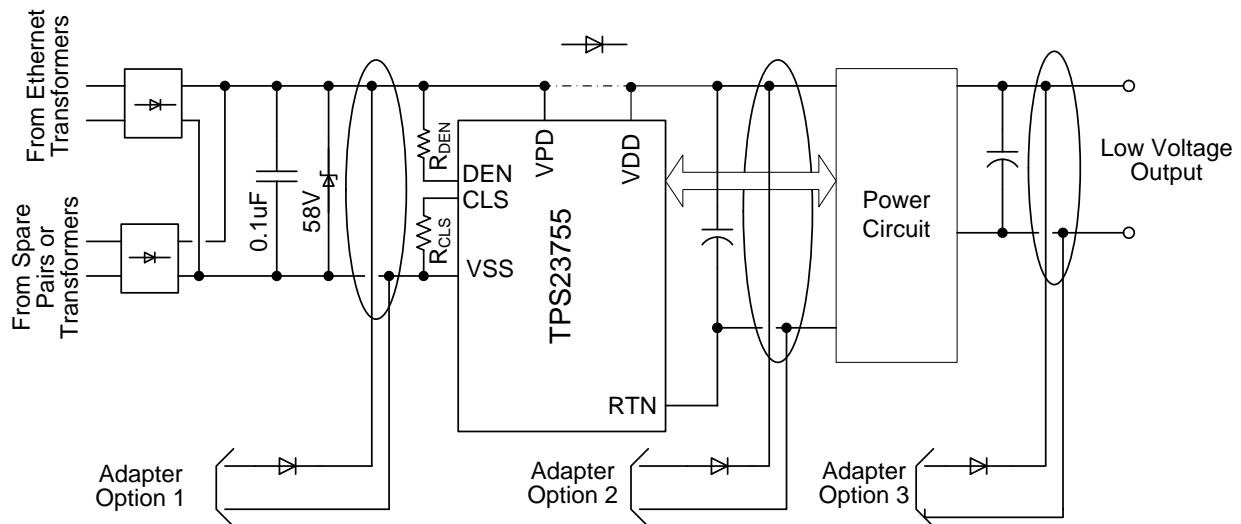

The hotswap switch is forced off under the following conditions:

- $V_{DEN} \leq V_{PD\_DIS}$  when  $V_{VPD-VSS}$  is in the operational range
- PD over temperature
- $V_{VPD-VSS} < PoE$  UVLO (approximately 31 V).

## Device Functional Modes (continued)

### 8.4.9 Adapter ORing

Many PoE-capable devices are designed to operate from either a wall adapter or PoE power. A local power solution adds cost and complexity, but allows a product to be used if PoE is not available in a particular installation. While most applications only require that the PD operate when both sources are present, the TPS23755 device supports forced operation from either of the power sources. Figure 37 illustrates three options for diode ORing external power into a PD. Only one option would be used in any particular design. Option 1 applies power to the device input, option 2 applies power between the device PoE section and the power circuit, and option 3 applies power to the output side of the converter. Each of these options has advantages and disadvantages. Many of the basic ORing configurations and much of the discussion contained in the application note *Advanced Adapter ORing Solutions using the TPS23755*, (SLVA306), apply to the TPS23755.

**Figure 37. ORing Configurations**

Preference of one power source presents a number of challenges. Combinations of adapter output voltage (nominal and tolerance), power insertion point, and which source is preferred determine solution complexity. Several factors contributing to the complexity are the natural high-voltage selection of diode ORing (the simplest method of combining sources), the current limit implicit in the PSE, PD inrush, and protection circuits (necessary for operation and reliability). Creating simple and seamless solutions is difficult if not impossible for many of the combinations. However, the TPS23755 device offers several built-in features that simplify some combinations.

Several examples demonstrate the limitations inherent in ORing solutions. Diode ORing a 48-V adapter with PoE (option 1) presents the problem that either source might be higher. A blocking switch would be required to assure which source was active. A second example is combining a 12-V adapter with PoE using option 2. The converter draws approximately four times the current at 12 V from the adapter than it does from PoE at 48 V. Transition from adapter power to PoE may demand more current than can be supplied by the PSE. The converter must be turned off while  $C_{BULK}$  capacitance charges, with a subsequent converter restart at the higher voltage and lower input current. A third example is use of a 12-V adapter with ORing option 1. The PD hotswap would have to handle four times the current, and have 1/16 the resistance (be 16 times larger) to dissipate equal power. A fourth example is that MPS is lost when running from the adapter, causing the PSE to remove power from the PD. If adapter power is then lost, the PD stops operating until the PSE detects and powers the PD.

The TPS23755 has a unique feature that can be used to achieve seamless transition while applying option 3. It provides adapter priority by reducing the DC-DC output voltage when the adapter voltage is present. An optocoupler is typically driven from the secondary side of the converter when the adapter voltage is present, which commands the converter voltage to go down to a predetermined voltage level, by use of pins AUX\_D and AUX\_V. This voltage level is lower than the minimum adapter voltage to ensure priority. The DC-DC converter stays in operation, which with appropriate minimum loading can ensure the PSE power will be maintained, to ensure there will be no output power interruption next time the adapter voltage goes down.

### Device Functional Modes (continued)

The IEEE standards require that the PI conductors be electrically isolated from ground and all other system potentials not part of the PI interface. The adapter must meet a minimum 1500-Vac dielectric withstand test between the output and all other connections for options 1 and 2. The adapter only needs this isolation for option 3 if it is not provided by the converter.

Adapter ORing diodes are shown for all the options to protect against a reverse-voltage adapter, a short on the adapter input pins, and damage to a low-voltage adapter. ORing is sometimes accomplished with a MOSFET in option 3.

## 9 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

The TPS23755 supports power supply topologies that require a single PWM gate drive with current-mode control. [Figure 38](#) provides an example of a simple diode rectified primary-side-regulated flyback converter.

### 9.2 Typical Application

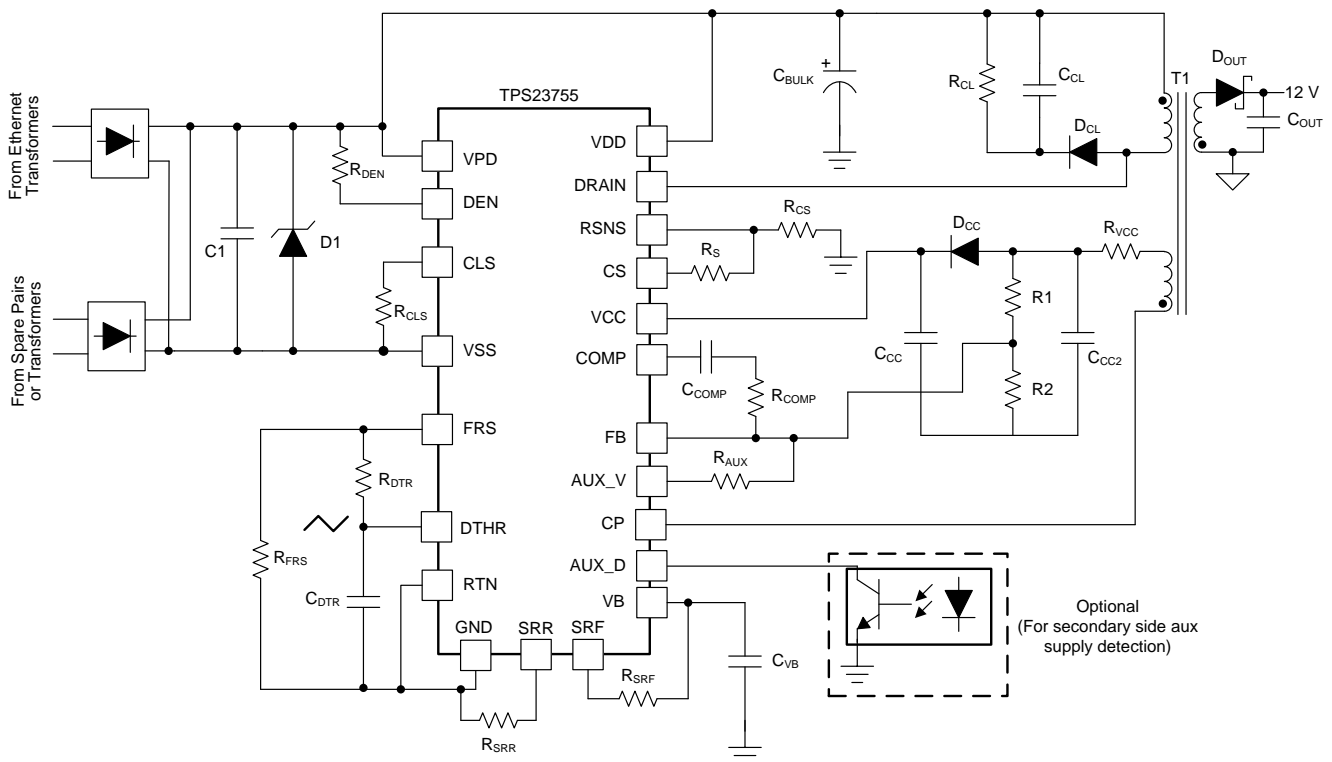

Figure 38. Basic TPS23755 Implementation

Typical Application (continued)

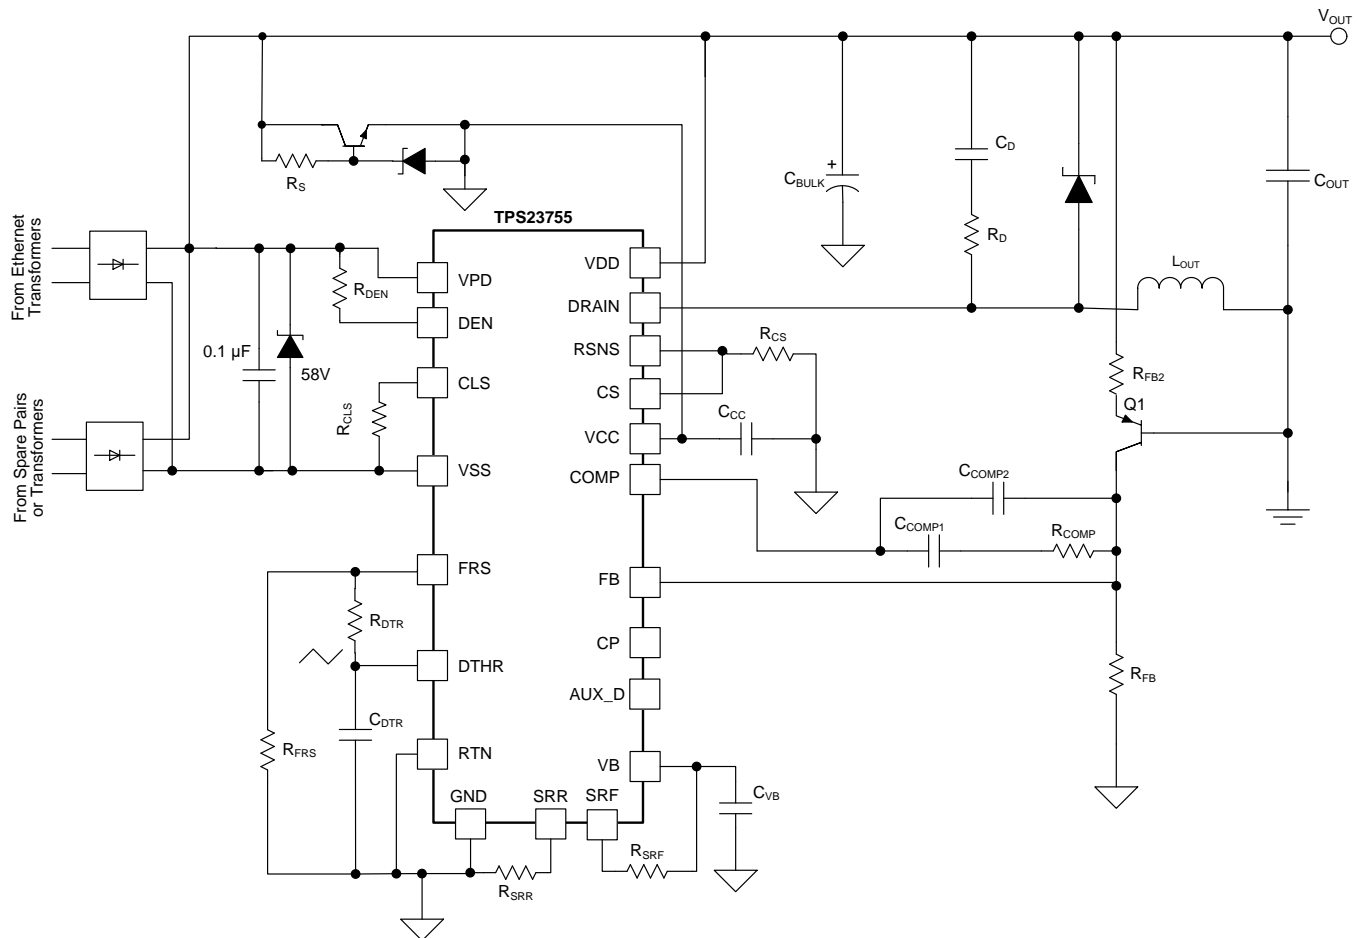

Figure 39. Simplified Buck Application

9.2.1 Design Requirements

Selecting a converter topology along with a design procedure is beyond the scope of this applications section. The TPS23755 is optimized for primary-side-regulated diode rectified flyback topologies for 12 V outputs or higher due to its good balance of high efficiency and output regulation. Typical applications use post regulation to power the system load's lower voltage rails. The TPS23755 can also be used in non-isolated buck topology application like shown in Figure 39.

Examples to help in programming the TPS23755 in a primary-side regulated flyback are shown below. For more specific converter design examples refer to the TPS23755EVM-894 EVM: Evaluation Module for TPS23755.

Table 3. Design Parameters

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>POWER INTERFACE</b>					
Input voltage	Applied to the PoE Input	37		57	V
	Applied to the Secondary Input		12		V
Detection voltage	At device terminals	2.7		10.1	V
Classification voltage	At device terminals	14.5		20.5	V
Classification current	$R_{CLASS} = 45.3 \Omega$	26.5		29.3	mA
Inrush current-limit			140		mA
Operating current-limit			550		mA

## Typical Application (continued)

**Table 3. Design Parameters (continued)**

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>DC-TO-DC CONVERTER</b>					
Output voltage	$V_{IN} = 48\text{ V}$ , $I_{LOAD} \leq I_{LOAD(max)}$		12		V
Output current	$37\text{ V} \leq V_{IN} \leq 57\text{ V}$		1		A
Output ripple voltage peak-to-peak	$V_{IN} = 48\text{ V}$ , $I_{LOAD} = 1\text{ A}$		50		mV
Efficiency, end-to-end	$V_{IN} = 48\text{ V}$ , $I_{LOAD} = 100\text{mA}$		78		%
	$V_{IN} = 48\text{ V}$ , $I_{LOAD} = 500\text{mA}$		86		
	$V_{IN} = 48\text{ V}$ , $I_{LOAD} = 1\text{ A}$		87		
Switching frequency			250		kHz

### 9.2.2 Detailed Design Procedure

#### 9.2.2.1 Input Bridges and Schottky Diodes

Using Schottky diodes instead of PN junction diodes for the PoE input bridges reduces the power dissipation in these devices by about 30%. There are, however, some things to consider when using them. The IEEE standard specifies a maximum backfeed voltage of 2.8 V. A 100-k $\Omega$  resistor is placed between the unpowered pairs and the voltage is measured across the resistor. Schottky diodes often have a higher reverse leakage current than PN diodes, making this a harder requirement to meet. To compensate, use conservative design for diode operating temperature, select lower-leakage devices where possible, and match leakage and temperatures by using packaged bridges.

Schottky diode leakage currents and lower dynamic resistances can impact the detection signature. Setting reasonable expectations for the temperature range over which the detection signature is accurate is the simplest solution. Increasing R<sub>DEN</sub> slightly may also help meet the requirement.

Schottky diodes have proven less robust to the stresses of ESD transients than PN junction diodes. After exposure to ESD, Schottky diodes may become shorted or leak. Care must be taken to provide adequate protection in line with the exposure levels. This protection may be as simple as ferrite beads and capacitors.

As a general recommendation, use 0.8A-1A, 100-V rated discrete or bridge diodes for the input rectifiers.

#### 9.2.2.2 Protection, D<sub>1</sub>

A TVS, D<sub>1</sub>, across the rectified PoE voltage per [Figure 38](#) must be used. A SMAJ58A, or equivalent, is recommended for general indoor applications. Adequate capacitive filtering or a TVS must limit input transient voltage to within the absolute maximum ratings. Outdoor transient levels or special applications require additional protection.

#### 9.2.2.3 Capacitor, C<sub>1</sub>

The IEEE 802.3at standard specifies an input bypass capacitor (from VDD to VSS) of 0.05  $\mu\text{F}$  to 0.12  $\mu\text{F}$ . Typically a 0.1  $\mu\text{F}$ , 100 V, 10% ceramic capacitor is used.

#### 9.2.2.4 Detection Resistor, R<sub>DEN</sub>

The IEEE 802.3at standard specifies a detection signature resistance, R<sub>DEN</sub> between 23.7 k $\Omega$  and 26.3 k $\Omega$ , or 25 k $\Omega$   $\pm$  5%. Typically a 24.9 k $\Omega$   $\pm$  1% is used.

#### 9.2.2.5 Classification Resistor, R<sub>CLS</sub>

Connect a resistor from CLS to VSS to program the classification current according to the IEEE 802.3at standard. The class power assigned should correspond to the maximum average power drawn by the PD during operation. Select R<sub>CLS</sub> according to [Table 2](#). For example, Class 3 applications should use a 45.3  $\Omega$  resistor for R<sub>CLS</sub>.

### 9.2.2.6 Bulk Capacitance, $C_{BULK}$

The bulk capacitance,  $C_{BULK}$  must furnish input transients during heavy loads and long cable length conditions. It also helps with stability on the DC/DC converter. It is recommended to use a minimum 10  $\mu$ F, electrolytic capacitor.

### 9.2.2.7 Output Voltage Feedback Divider, $R_{AUX}$ , $R_1$ , $R_2$

$R_1$ ,  $R_2$  and  $R_{AUX}$  set the output voltage of the bias winding of the converter. For applications that do not use AUX\_D functionality,  $R_{AUX}$  should not be populated and Equation 5 should be used.

$$V_{VCC} = \frac{V_{REFC} (R_1 + R_2)}{R_2} \quad (5)$$

For secondary side adapter priority applications, the DC/DC output voltage can be set lower than the adapter voltage by pulling AUX\_D to RTN. Equation 6 should be used first to determine the lower output voltage when adapter is present.

$$V_{VCC} = \frac{V_{REFC} (R_1 + R_2)}{R_2}$$

when Aux\_D is LOW. (6)

Then  $R_{aux}$  can be calculated using Equation 7 to set the nominal output voltage of the bias winding.

$$V_{VCC} = \frac{V_{REFC} (R_1 R_{AUX} + R_1 R_2 + R_2 R_{AUX})}{R_2 R_{AUX}}$$

when Aux\_D is HIGH. (7)

When transitioning from the normal operating output voltage to a lower output voltage when Aux\_D is pulled LOW, switching may stop until the VCC voltage can reduce its voltage to the lower VCC voltage. The output voltage may drop during this time due to the loss of switching. Typically this is not a concern since the adapter is providing power to the load. A combination of adding a dummy load in parallel with  $C_{CC}$  and increasing the secondary output capacitance can minimize the time that switching stops.

In applications that use smooth transition between adapter the PoE, circuitry should be added to keep the PSE connected to the PD and the converter operational while maintaining adapter priority. It is recommended to refer to the TPS23755EVM-894.

### 9.2.2.8 Setting Frequency, $R_{FRS}$

The converter switching frequency in PWM mode is set by connecting resistor,  $R_{FRS}$  from the FRS pin to RTN. For a converter that requires a 250 kHz switching frequency and using Equation 8

$$R_{FRS} (k\Omega) = \frac{15000}{f_{SW} (kHz)} = \frac{15000}{250 \text{ kHz}} = 60 \text{ k}\Omega \quad (8)$$

A standard 60.4 k $\Omega$  resistor should be used.

### 9.2.2.9 Frequency Dithering, $R_{DTR}$ and $C_{DTR}$

For optimum EMI performance,  $C_{DTR}$  and  $R_{DTR}$  should be selected as described in Frequency Dithering for Spread Spectrum Applications in Equation 9 and Equation 10.

$$C_{DTR} (nF) = \frac{3}{2.052 \times f_m (Hz)} \times R_{FRS} (\Omega) = \frac{3}{2.052 \times 11000 \text{ Hz}} \times 60.4 \text{ k}\Omega = 2.2 \text{ nF} \quad (9)$$

$$R_{DTR} (\Omega) = \frac{0.513 \times R_{FRS} (\Omega)}{\%DTHR} = \frac{0.513 \times 60.4 \text{ k}\Omega}{0.132} = 235 \text{ k}\Omega \quad (10)$$

A standard 237 kΩ resistor should be used.

#### 9.2.2.10 Transformer design, $T_1$

The turns ratio and primary inductance are important parameters to consider in a flyback transformer. The turns ratio act to limit the max duty cycle and reduce stress on the secondary components while the primary inductance sets the current ripple. In CCM operation, the higher inductance allows for a reduced current ripple which can help with EMI performance and noise.

For primary-side regulated flyback converters, the transformer construction is important to maintain good regulation on the secondary output. It is recommended to use LDT0950 for 12 V applications.

#### 9.2.2.11 Current Sense Resistor, $R_{CS}$

$R_{CS}$  should be chosen based on the peak primary current at the desired output current limit.

$$R_{CS} = \frac{V_{CSMAX}}{I_{Pk-Primary}} \quad (11)$$

#### 9.2.2.12 Current Slope Compensation, $R_S$

$R_S$  may be used if the internally provided slope compensation is not enough. The down slope of the reflected secondary current through the current sense resistor at each switching period is determined and a percentage (typically 50%-75%) of it will define  $V_{SLOPE}$ . Using LDT0950, it is recommended to start with 251 mV and use [Equation 12](#).

$$R_S (\Omega) = \frac{\left[ V_{SLOPE_D} (mV) - \left( \frac{V_{SLOPE} (mV)}{D_{MAX}} \right) \right]}{\frac{I_{SL_{EX}} (\mu A)}{D_{MAX}}} \times 1000 = \frac{\left[ 251 mV - \left( \frac{155 mV}{78.5\%} \right) \right]}{\frac{42 \mu A}{78.5\%}} \times 1000 = 1 k\Omega \quad (12)$$

#### 9.2.2.13 Bias Supply Requirements, $C_{CC}$ , $D_{CC}$

Advanced startup in the TPS23755 allows for relatively low capacitance on the bias circuit. It is recommended to use a 1 μF 10% 25 V ceramic capacitors on  $C_{CC}$ .  $D_{CC}$  can be a low cost, general-purpose diode. It is recommended to use MMSD4148 diode (100 V, 200 mA).

#### 9.2.2.14 Switching Transformer Considerations, $R_{VCC}$ and $C_{CC2}$

$R_{VCC}$  helps to reduce peak charging from the bias winding. Reduced peak charging becomes especially important when tuning hiccup mode operation during output overload. A typical value for  $R_{VCC}$  in Class 3 PoE PD applications while maintaining a suitable load regulation is 10 ohms.

#### 9.2.2.15 Primary FET Clamping, $R_{CL}$ , $C_{CL}$ , and $D_{CL}$

The stored energy in the leakage inductance of the power transformer can cause ringing during the primary FET turnoff. The snubber must be chosen to mitigate primary FET overshoot and oscillation while maintaining high overall efficiency.

It is recommended to use 39 kΩ (125 mW) for  $R_{CL}$  and 0.1 μF (100 V) for  $C_{CL}$ .

$D_{CL}$  should be an ultra-fast diode with a short forward recovery recovery time allowing the snubber to turn on quickly. The 200 V / 1 A rated diode with a recovery time approximately 25 ns or better is recommended.

#### 9.2.2.16 Converter output capacitance, $C_{OUT}$

The output capacitor is considered as part of the overall stability of the converter, the output voltage ripple, and the load transient response. The output capacitor needs to be selected based on the most stringent of these criteria. The minimum capacitance is typically determined by the output voltage ripple shown in [Equation 13](#).

$$C_{OUT} > \frac{I_{OUT} (A) \times D_{max}}{V_{Ripple} (V) \times f_{SW} (Hz)}$$

where  $D_{max}$  is the calculated operating max duty cycle shown in [Equation 14](#) (13)

$$D_{max} = \frac{(V_{OUT} + V_{Diode}) \times N_{PS}}{V_{IN} (min) + (V_{OUT} + V_{Diode}) \times N_{PS}} \quad (14)$$

For strict load transient requirements, the  $C_{OUT}$  cap may need to be increased. The TPS23755EVM-894 uses two 22 uF ceramic capacitors for an optimized load transient response.

### 9.2.2.17 Secondary Output Diode Rectifier, $D_{OUT}$

The output rectifier diode must provide low forward voltage drop at the secondary peak current. Consideration must be given to a safe operating area during output overload conditions.

For a 12 V output, PDS360-13 in a high thermal performance package (60 V reverse voltage, 3-A continuous current max,  $V_f = -0.62$  V max at 3A ) is used in the TPS23755EVM-894.

### 9.2.2.18 Slew rate control, $R_{SRF}$ and $R_{SRR}$

$R_{SRF}$  and  $R_{SRR}$  minimize primary drain-source oscillations and help optimize EMI performance at high frequencies, the value chosen should be within the recommend operating conditions table in [Recommended Operating Conditions](#). It is recommended to start with 10 ohms for  $R_{SRF}$  and 10 ohms for  $R_{SRR}$  then adjust accordingly during bench and EMI testing.

### 9.2.2.19 Shutdown at Low Temperatures, $D_{VDD}$ and $C_{VDD}$

For applications operating near  $-10^{\circ}\text{C}$  or less, there may be some extra switching cycles during removal of the PoE input or during shutdown. It is acceptable for most applications; however, for a more monotonic shutdown of the output voltage during power removal, it is recommended to use  $D_{VDD}$  and  $C_{VDD}$  as shown in [Figure 40](#).  $D_{VDD}$  can be MMSD4148 and  $C_{VDD}$  can be 0.22 uF 100 V capacitor.

## 10 Power Supply Recommendations

The TPS23755 converter should be designed such that the input voltage of the converter is capable of operating within the IEEE802.3at recommended input voltage as shown in [Figure 31](#) and the minimum operating voltage of the adapter if applicable.

## 11 Layout

### 11.1 Layout Guidelines

The TPS23755 IC's layout footprint shown in the Example Board Layout should be strictly followed. The below list are key highlights for layout consideration around the TPS23755.

- Pin 22 of the TPS23755 is omitted from the IC to ensure high voltage clearance from Pin 24 (DRAIN). Therefore, the Pin 22 footprint should be removed when laying out the TPS23755.
- It is recommended having at least 8 vias (VSS) connecting the exposed thermal pad through a top layer plane (2 oz copper recommended) to a bottom VSS plane (2 oz. copper recommended) to help with thermal dissipation.
- The Pin24 of the TPS23755 should be near the power transformer and the current sense resistor should be close to Pin 1 of the TPS23755 to minimize the primary loop.

The layout of the PoE front end should follow power and EMI or ESD best-practice guidelines. A basic set of recommendations includes:

- Parts placement must be driven by power flow in a point-to-point manner; RJ-45, Ethernet transformer, diode bridges, TVS and 0.1  $\mu$ F capacitor, and TPS23755 converter input bulk capacitor.
- Make all leads as short as possible with wide power traces and paired signal and return.
- No crossovers of signals from one part of the flow to another are allowed.
- Spacing consistent with safety standards like IEC60950 must be observed between the 48 V input voltage rails and between the input and an isolated converter output.
- Use large copper fills and traces on SMT power-dissipating devices, and use wide traces or overlay copper fills in the power path.

The DC-to-DC converter layout benefits from basic rules such as:

- Having at least 4 vias (VDD) near the power transformer pin connected to VDD through multiple layer planes to help with thermal dissipation of the power transformer.
- Having at least 6 vias (secondary ground) near the power transformer pin connected to secondary ground through multiple layer planes to help with thermal dissipation of the power transformer.
- Pair signals to reduce emissions and noise, especially the paths that carry high-current pulses, which include the power semiconductors and magnetics.
- Minimize the trace length of high current power semiconductors and magnetic components.
- Where possible, use vertical pairing.
- Use the ground plane for the switching currents carefully.
- Keep the high-current and high-voltage switching away from low-level sensing circuits including those outside the power supply.
- Maintain proper spacing around the high-voltage sections of the converter.

### 11.2 Layout Example

[Figure 49](#) and [Figure 50](#) show the top and bottom layer and assemblies of the TPS23755EVM-894 as a reference for optimum parts placement.

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## TAPE AND REEL INFORMATION

### QUADRANT ASSIGNMENTS FOR PIN 1 ORIENTATION IN TAPE

\*All dimensions are nominal

Device	Package Type	Package Drawing	Pins	SPQ	Reel Diameter (mm)	Reel Width W1 (mm)	A0 (mm)	B0 (mm)	K0 (mm)	P1 (mm)	W (mm)	Pin1 Quadrant
TPS23755RJJR	VSON	RJJ	23	3000	330.0	12.4	4.25	6.25	1.15	8.0	12.0	Q1
TPS23755RJJT	VSON	RJJ	23	250	180.0	12.4	4.25	6.25	1.15	8.0	12.0	Q1

**TAPE AND REEL BOX DIMENSIONS**
